Data Supplement for Bromis et al., Meta-Analysis of 89 Structural MRI Studies in Posttraumatic Stress Disorder and Comparison to Major Depressive Disorder. Am J Psychiatry (doi: 10.1176/appi.ajp.2018.17111199)

Methods

MEDLINE (Pubmed) search term

The following MEDLINE search term was used and was completed on July 4th 2016. MEDLINE was used because it has excellent coverage of MRI studies of clinical populations, particularly from 1990s forward.

(("Stress Disorders, Traumatic"[MeSH] OR “PTSD” OR “post traumatic stress” OR "posttraumatic stress") AND MRI)

The search terms in the parenthesis were to catch all studies either tagged by the commonly used MeSH term "Stress Disorders, Traumatic" or the free text terms mentioned. Using the text MRI in pubmed then automatically maps this to the more broader search term:
"magnetic resonance imaging"[MeSH Terms] OR ("magnetic"[All Fields] AND "resonance"[All Fields] AND "imaging"[All Fields]) OR "magnetic resonance imaging"[All Fields] OR "mri"[All Fields]

By hand searching through previous reviews and meta-analyses we identified a number of studies however they were all duplicated from the MEDLINE search except for 5 studies (see Figure S1). Further details of how studies were reviewed can be found at http://www.ptsdmri.uk which includes a list of the 800 studies in the literature search, indicating which studies were included/excluded and the reasons for exclusion.

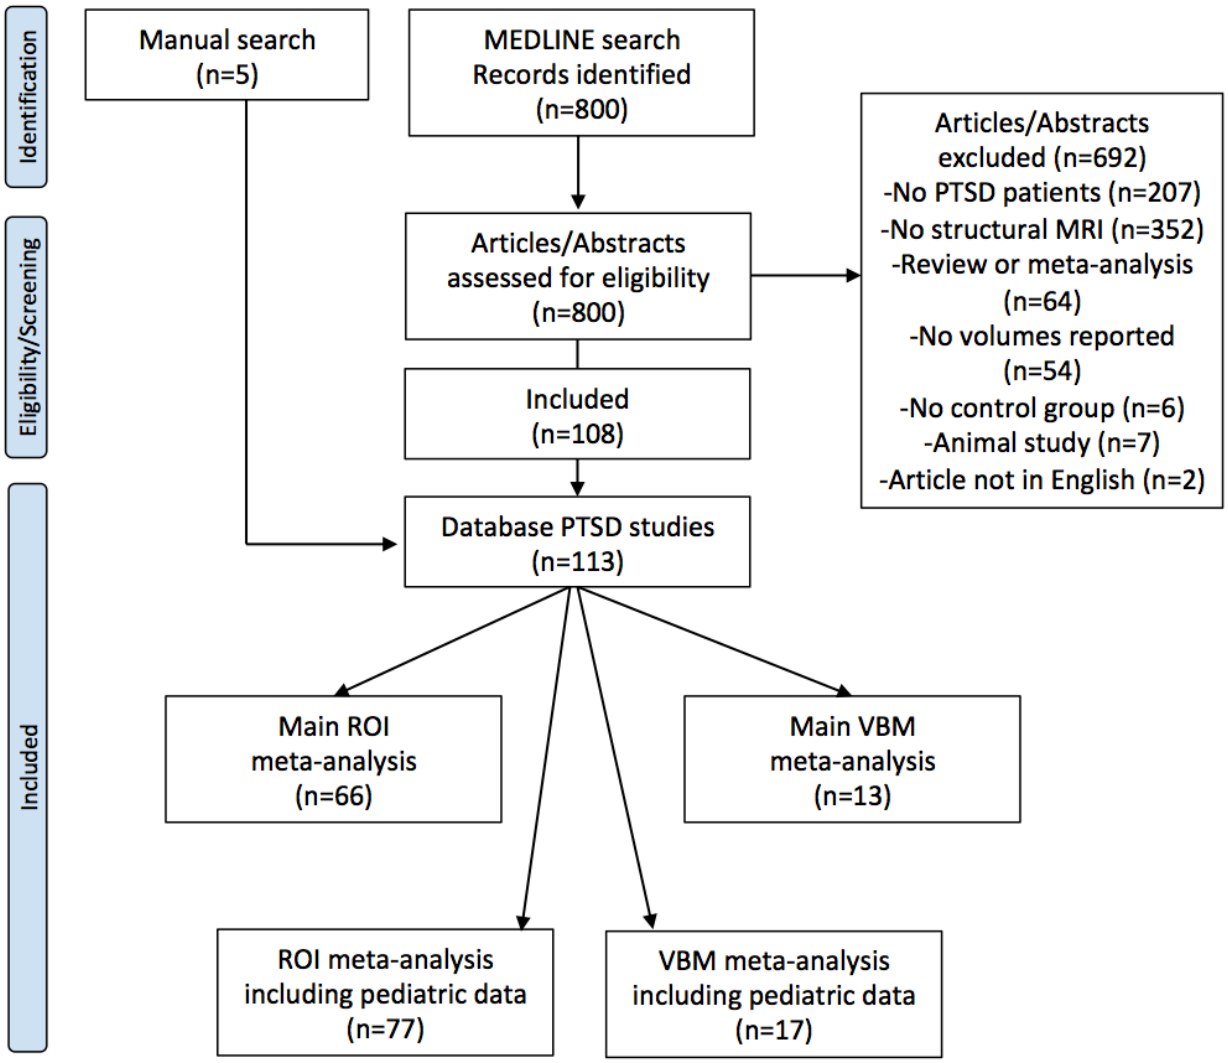

Figure S1: Adapted PRISMA flowchart showing study inclusion. The number of studies included in the meta-analysis including pediatric data is 89 studies (77 region-of-interest studies plus 17 VBM studies, minus 5 overlapping studies)

Database of imaging studies in Post-Traumatic Stress Disorder

Studies were included in the database if patients were diagnosed with PTSD according to standardized diagnostic criteria, and for region-of-interest studies volumetric data was presented in terms of group means and standard deviations, and for VBM studies spatial coordinate data was presented. Control groups differed between studies, the largest proportion used non-traumatised-controls, other studies used a Traumatised-controls and a smaller proportion included two control groups, non-traumatised-

controls and Traumatised-controls. One hundred and thirteen studies satisfied all the criteria and were incorporated in the database (80 region-of-interest studies, 23 VBM studies, and 10 studies presenting both region-of-interest and VBM data).

Data recorded in the database

The following data from each study were included in the database: number of PTSD patients and number of controls, diagnostic classification system used, mean age of patients and controls, number of males and females in the patient and control groups, mean age of illness onset, time since trauma, duration of illness, mean score from Clinician-Administered PTSD Scale (CAPS),[1] and the type of control group used. For medication we recorded the number of patients described as drug free (not necessarily medication naive), using antidepressants, mood stabilizers, or antipsychotics. From the MRI acquisition we recorded slice thickness and magnetic field strength.

Post-traumatic Stress Disorder Region-of-interest Meta-analysis

In order to ensure that the selection of brain structures for the meta-analysis was not biased, we recorded all regions that had been investigated in the 90 studies reporting region-of-interest data included in the database. As observed in previous meta-analyses, exact anatomic definitions of brain structures varied across studies. Where data was unclear or we suspected sample overlap between studies we contacted the authors. Due to the limited information provided by the case-control studies we did not attempt to assess bias in the sample obtainment, although we did analyse publication bias (see below). To ensure that the meta-analysis was sufficiently powered, we included brain regions for which the volume mean and standard deviation in both patient and control groups were reported by three or more studies

Region of interest Sensitivity Analysis

To test how robust the results were to variations in the meta-analysis method, 4 sensitivity analyses were conducted for the region of interest meta-analysis.

(1) For a given region, some authors separately reported left and right measures while others included only the combined total measure. For studies that only reported left and right measurements, we used a previously described method[2] to calculate the mean and standard deviation for the total volume. The method requires an estimate of the correlation coefficient between the left and right volumes. This coefficient was set to 0.8 but was varied in the sensitivity analysis as 0, 0.5 and 1.0.

(2) While most individual studies reported absolute volumes of brain structures a small number of studies reported volumes divided by intracranial volume. In the main analysis we combined studies reporting absolute volumes, and volumes divided by intracranial volume. In the second sensitivity analysis we excluded volumes divided by intracranial volume

(3) While most individual studies reported volumes of brain structures a small number of cortical regions were reported in terms of thickness. For these regions we combined studies reporting thickness and volume, but excluded thickness measures in the third sensitivity analysis.

(4) In the main analysis we excluded studies with paediatric patients to reduce heterogeneity, in the fourth sensitivity analysis we included 11 paediatric studies.

Combining study estimates

The meta-analysis for each brain structure was performed by using meta-analytical equations entered into Excel (see www.ptsdmri.uk). This technique has the advantage of efficient data entry, being publicly available while using identical equations to the METAN command in STATA,[3] which is commonly used in meta-analyses publications. In terms of validation, the method been used in parallel with STATA in three previous meta-analyses[4, 5, 6] and produced the same results.

Combining patient subgroups

A minority of studies reported measures from subgroups of patients and their own matched control group. In this case, we considered subgroups as equivalent to separate studies. Similarly, when studies reported men and women in the patient group separately, we incorporated the results in the meta-analysis as two different studies. This method has been used in a previous meta-analysis.[7] Because the meta-analyses examined a large number of regions and included sub-meta-analyses it is susceptible to type I errors. Therefore, results that survive Bonferroni correction for multiple comparisons are indicated.

Voxel Based Morphometry Meta-analysis using Seed-based d Mapping (SDM)

The following inclusion criteria were applied to the database of 113 studies: 1) gray matter VBM study comparing adult patients with PTSD to either non-traumatised-controls or traumatised-controls; 2) results presented in Talairach or MNI coordinates; 3) studies were only included if a whole brain analysis was performed rather than a small volume correction to ensure no bias in the regions reported. Thirteen

studies met inclusion criteria and are listed in Table S1. We emailed all study authors who used SPM (Statistical Parametric Mapping) to process their data for a 'T-map' image comparing PTSD gray matter volume to the control group. 'T-maps' are three dimensional maps comprising statistical data of volume differences in thousands of voxels in the brain and provide far more detailed information than significant coordinates reported in studies. However, SDM allows both T-maps and coordinates to be combined in a single meta-analysis and the methodology reported in detail by Radua et al.[8] We received 6 T-maps from 6 independent studies and these were included in the meta-analyses. In addition to the main meta-analysis comparing PTSD to all controls, three additional VBM analyses were conducted: 1) comparing the PTSD group with non-traumatised-controls only 2) comparing the PTSD group with traumatised-controls only, 3) comparing PTSD group with all controls and widening the criteria to include paediatric studies. T-maps and coordinates signifying gray matter volume changes from where we were unable to obtain T-maps were extracted from relevant studies and analysed using Seed-based d Mapping[8] (SDM version 5.14, http://www.sdmproject.com). For studies where coordinate data was used, these were convolved with a Gaussian kernel (FWHM=20mm) in order to optimally compensate the sensitivity and specificity of the analysis. As is standard in SDM analyses, the number of randomizations were set to 100 and a threshold was set at $p<0.005$ as well as a cluster-level threshold of 10 voxels in order to increase sensitivity and correctly control false-positive rate.[8] A jackknife sensitivity analysis was performed in order to assess the robustness of the results which was achieved by excluding one study in each of the analyses.

Results

Region of interest sensitivity analysis:

4) Including paediatric data

Eleven pediatric studies were included in the region of interest meta-analysis. In the analysis comparing PTSD patients to all controls there were 11 new significant results: smaller frontal lobe, gray matter, cerebral volume, right and total temporal lobe, right amygdala, cerebellum, vermis, and the anterior midbody, posterior midbody and isthmus of corpus callosum (Table S5, Figure S5a-S5b). The reduction in the volume of the left anterior cingulate was no longer significant. In the PTSD vs non-traumatised-controls comparison, 11 new significant results emerged with the pediatric data: PTSD patients had significant smaller intracranial volume, right and total temporal lobe, total and left amygdala, cerebellum, vermis and anterior midbody, posterior midbody, isthmus and total cross sectional area of the corpus callosum (Table S6, Figure S6). There was no change in significance for the PTSD vs traumatised-controls or traumatised-controls vs non-traumatised-controls comparison.

Table S2. Meta-analysis of regional brain volumes comparing patients with post-traumatic stress disorder to non-trauma exposed controls. Bold indicates significant differences. S.S Bias = Small Study Bias, CI = confidence interval, Non-traumatised-controls = healthy non-trauma-exposed controls. *Result remained significant after Bonferroni correction for multiple comparisons of 26 brain structures. Leave-one-out analysis examines if the pooled effect size becomes non-significant when removing one effect size at a time; a value of 100% which is the most robust result indicates that the pooled effect size remains significant when 100% of effect sizes are removed in turn.

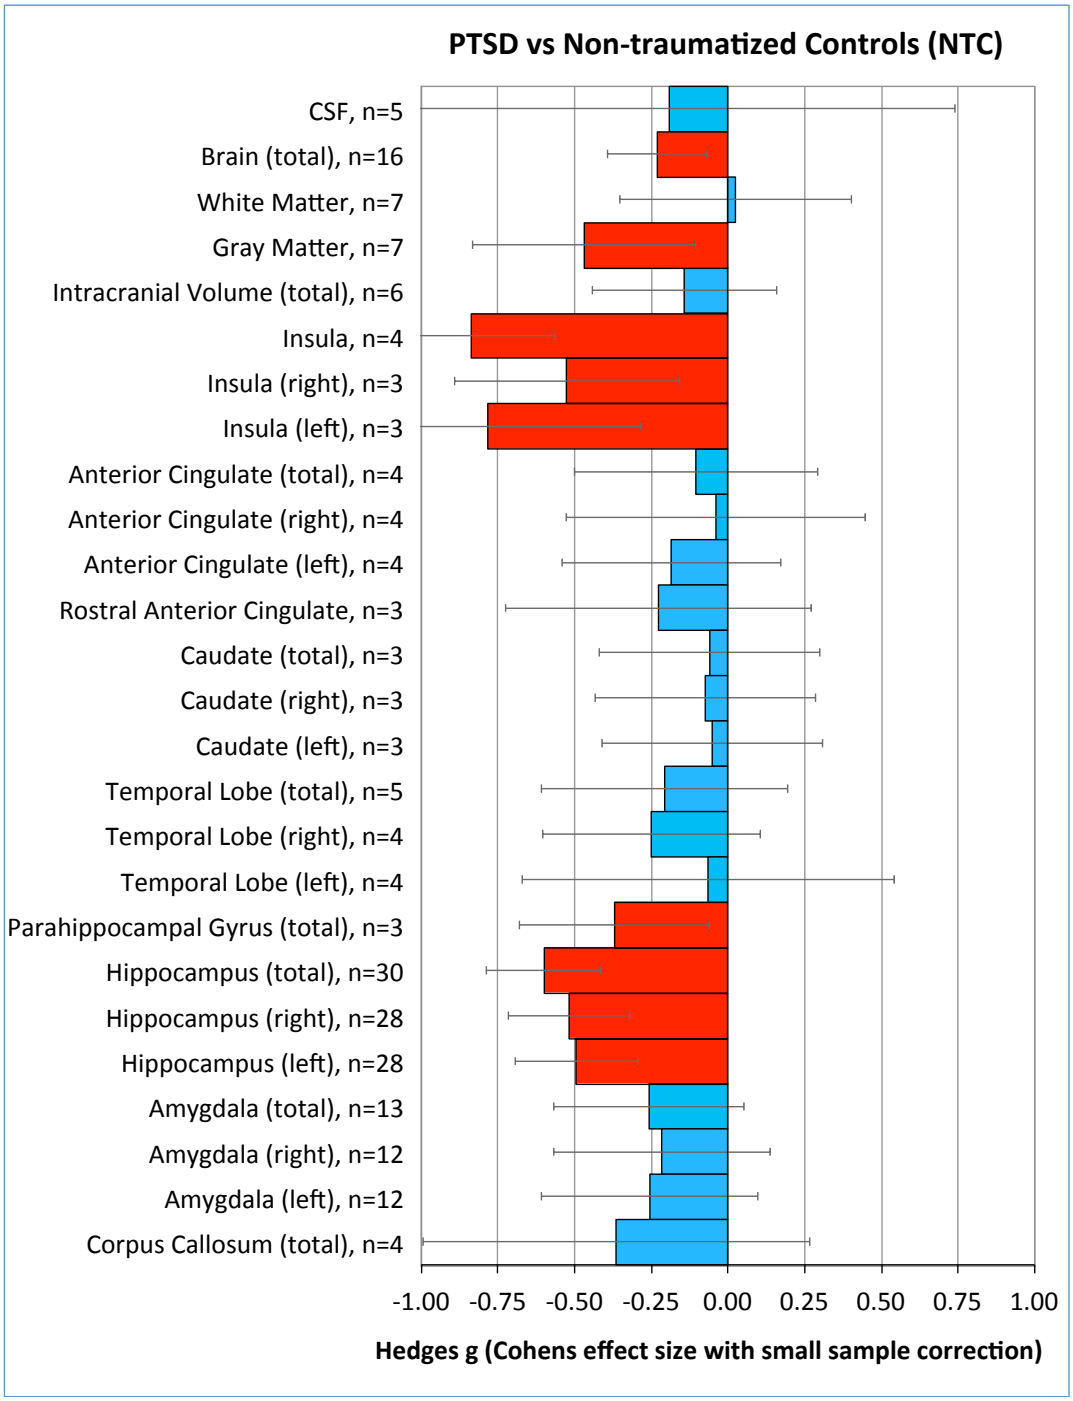

Figure S2. Meta-analysis of regional brain volumes comparing patients with post-traumatic stress disorder to non-traumatised control group. Hedges *g* (Cohen effect size with small sample correction) is shown for each structure, with 95% confidence intervals. The effect size is positive when the structure is larger in patients with PTSD compared with controls and negative when the structure is smaller in PTSD patients. Red indicates significant differences. The number of studies included in each meta-analysis is indicated with each structure. Non-traumatised-controls = healthy non-trauma exposed controls.

Table S5. Meta-analysis of regional brain volumes (including paediatric samples) comparing patients with post-traumatic stress disorder to controls. Brain regions are shown where pediatric data changes the effect size given in table 2. **Bold** indicates significant differences. S.S Bias = Small Study Bias. *Result remained significant after Bonferroni correction for multiple comparisons for 42 brain structures.

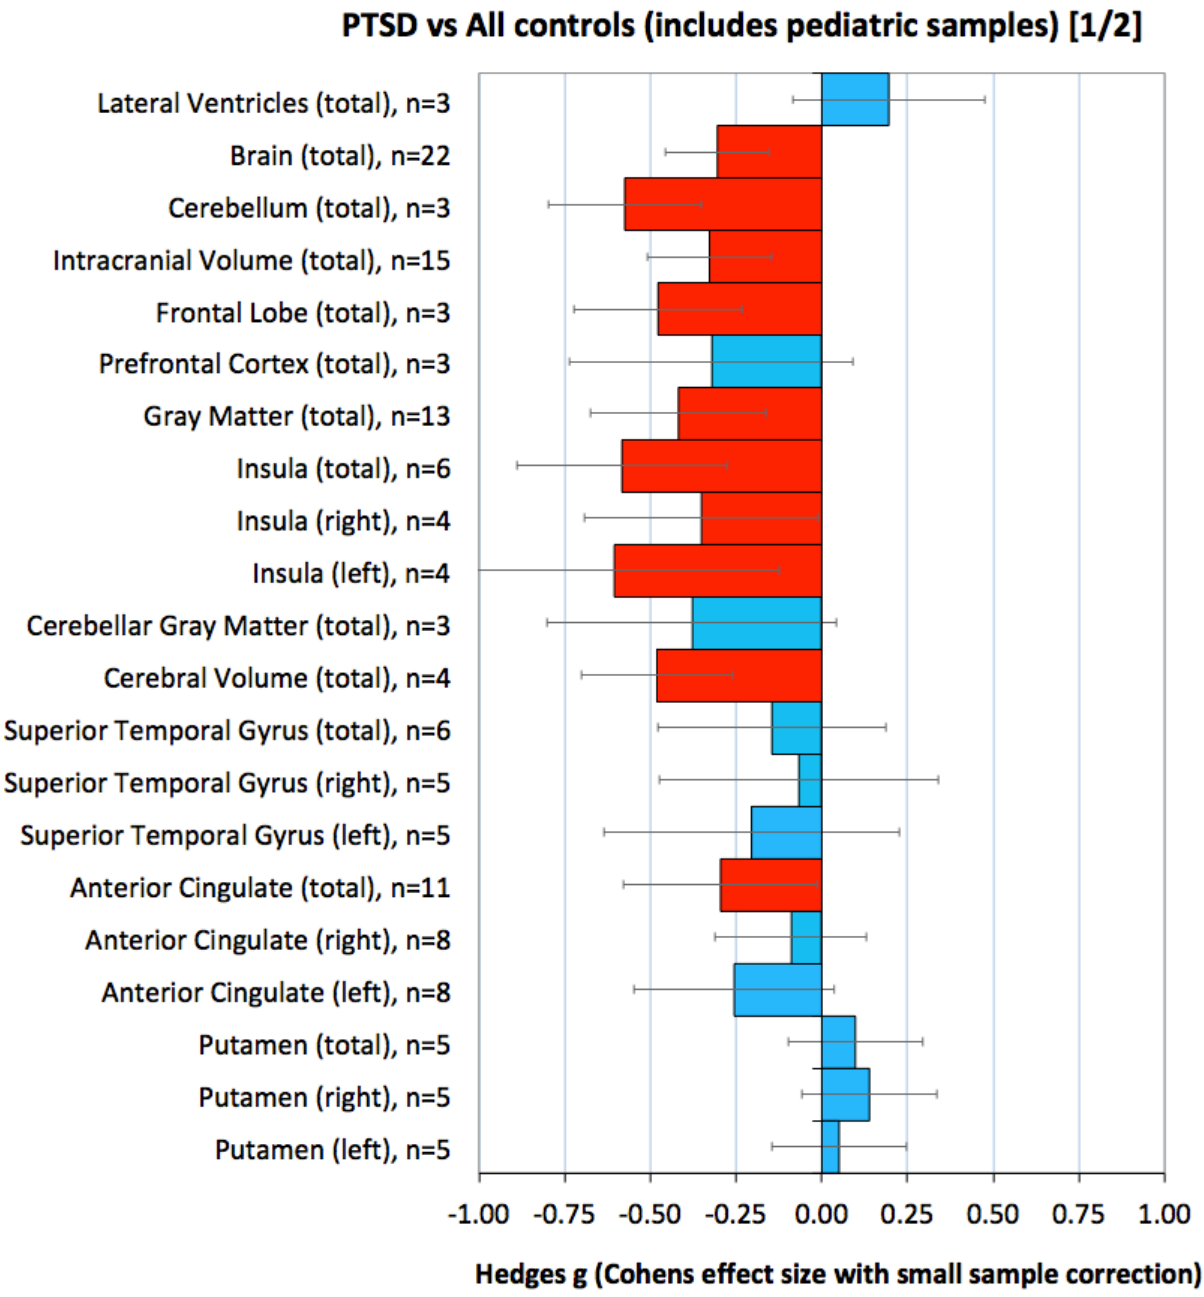

Figure S5a. Meta-analysis of regional brain volumes (including paediatric samples) comparing patients with post-traumatic stress disorder to controls. Hedges *g* (Cohen effect size with small sample correction) is shown for each structure, with 95% confidence intervals. The effect size is positive when the structure is larger in patients with PTSD compared with controls and negative when the structure is smaller in PTSD patients. Red indicates significant differences. The number of studies included in each meta-analysis is indicated for each structure.

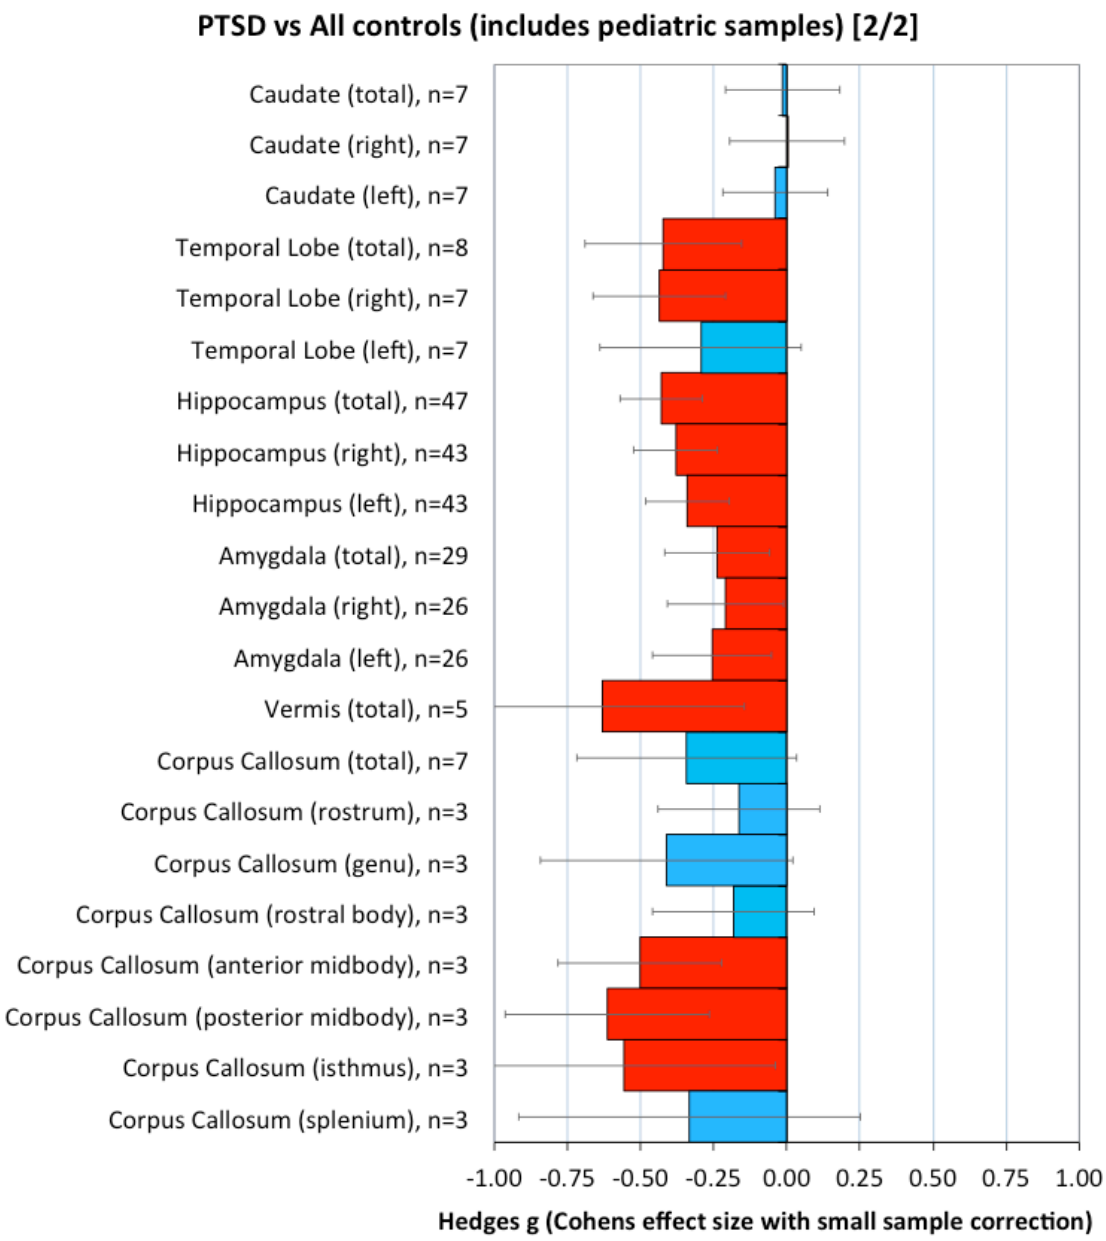

Figure S5b. Meta-analysis of regional brain volumes (including paediatric samples) comparing patients with post-traumatic stress disorder to controls. Hedges *g* (Cohen effect size with small sample correction) is shown for each structure, with 95% confidence intervals. The effect size is positive when the structure is larger in patients with PTSD compared with controls and negative when the structure is smaller in PTSD patients. Red indicates significant differences. The number of studies included in each meta-analysis is indicated for each structure.

Table S6. Meta-analysis of regional brain volumes (including paediatric samples) comparing patients with post-traumatic stress disorder to non-traumatised controls. Brain regions are shown where pediatric data changes the effect size given in table S2. Bold indicates significant differences. S.S Bias = Small Study Bias, CI = confidence interval, Non-traumatised-controls = healthy non-trauma-exposed controls. * Result remained significant after Bonferroni correction for multiple comparisons for 27 brain structures

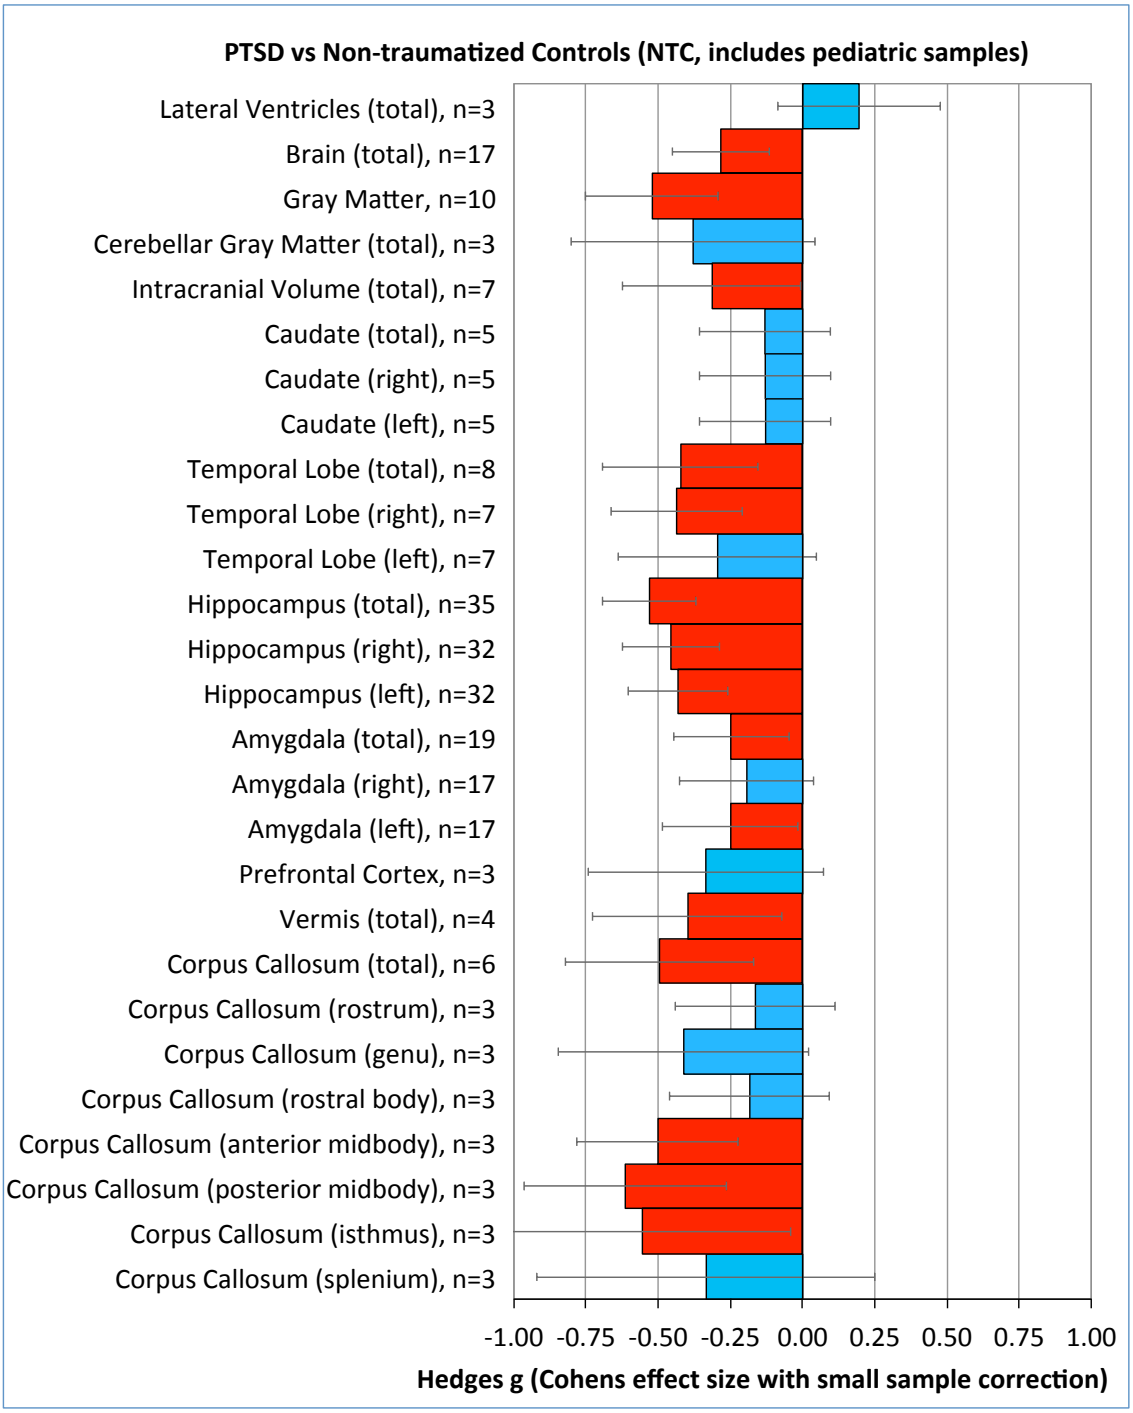

Figure S6. Meta-analysis of regional brain volumes (including paediatric samples) comparing patients with post-traumatic stress disorder to non-traumatized control group. Hedges *g* (Cohen effect size with small sample correction) is shown for each structure, with 95% confidence intervals. The effect size is positive when the structure is larger in patients with PTSD compared with controls and negative when the structure is smaller in PTSD patients. Red indicates significant differences. The number of studies included in each meta-analysis is indicated with each structure. Traumatised-controls = exposed to trauma but without PTSD.

Table S7. Meta-analysis Comparing Patients with PTSD vs Traumatised-controls (TC), (includes pediatric samples)

Table S8. Statistical Comparison of the present PTSD Meta-analysis With a previous Meta-analysis of Major-depressive-disorder[4]. The comparison is PTSD vs Non-traumatised-controls compared to Major-depressive-disorder vs controls. For the PTSD vs Major-depressive-disorder comparison, negative effect sizes indicate that the region is smaller in PTSD patients; positive effect sizes indicate that the region is smaller in Major-depressive-disorder patients.

Table S9 Regions of Significant Changes in GMV Between Patients with PTSD and NTC or TC group – SDM Analysis					
Regions	MNI coordinates X, Y, Z	SDM z-value	P-value	Number of voxels	Number of studies Jacknife Sensitivity analysis
Right anterior cingulate	6, 32, 28	4.507	<0.0001	2348	13
Left superior frontal gyrus, dorsoratelal	-26, 52, 20	3.425	<0.0001	763	13
Right fusiform gyrus	28, -38, -18	3.144	0.0005	86	12
Left amygdala	-28, -10, -18	2.806	0.002	58	8
Right amygdala	26, -2, -14	2.880	0.002	54	10
Left precentral gyrus	-48, 2, 42	3.078	0.0006	48	11
Right inferior temporal gyrus	56, -52, -8	2.980	0.001	28	9

L Amygdala	19	-0.28 (-0.57 to 0.00)	13	**-0.20 (-0.38 to -0.02)**

Table S13. Region of interest meta-analysis compared to VBM meta-analysis (Seed-based d Mapping (SDM)). When comparing the methodologies it is important to note that effect sizes are calculated differently in each method. For example the inclusion of coordinates results in the SDM meta-analysis tends to reduce the magnitude of effect sizes as non-significant findings are assumed to be zero, furthermore SDM calculates the average effect size of a number of voxels rather than effect size of a single region. Note that the right column of this table is different from the clusters shown in table S11. In this table effect sizes are given for an entire structure, while table S11 shows clusters or 'hot spots' within a structure. Thus while a significant small cluster was found in the left hippocampus in table S11, when the entire structure was considered there was no overall difference in volume.
